Live Strategy Recommendations

Intraday Options & Intraday Equity — based on current strategy.py code

Scores are grounded in actual signal logic, candle requirements, scoring formulas, and known code gaps.

INTRADAY OPTIONS — RANKED FOR LIVE USE

ATM_MULTI

Recommended #1 **Self-filtering** **Sideways-safe**

9/10
live suitability

Runs Momentum + ORB + VWAP Reversion internally. Only trades when two signals agree or when ATR confirms sideways + reversion. Returns NO_TRADE on conflict — protects capital automatically.

Candles needed	20 session candles	Signal fires when	Momentum + ORB agree, or ATR sideways + VWAP reversion
Conflict handling	Returns NO_TRADE — never forces an entry	Live risk	Lower trade frequency, misses some moves

Best for: unknown sessions, volatile opens, or when you are unsure of market character going in.

ATM_ORB

Recommended #2 **Early-session edge** **Simple logic**

8/10
live suitability

Waits for 15 full opening candles, then fires only on a clean close above/below that range. Single condition — no RSI, no VWAP drift to debate. Strength score is purely price distance from the range edge.

Candles needed	16 (fewest of all)	Signal fires when	Close breaks 15m high or low decisively
Conflict handling	N/A — one condition, no ambiguity	Live risk	False breakouts on flat/sideways opens

Best for: gap-and-go days, strong trending opens. Know by 9:31 whether the market has conviction before committing.

ATM_MOMENTUM

Trending days **Mid-day fade risk**

7/10
live suitability

Requires close above VWAP + RSI > 60 + breakout above recent 5-candle high simultaneously. Triple-condition strength score means fewer false fires, but also fires late in strong moves.

Candles needed	20 session candles	Signal strength	Sum of RSI deviation + VWAP gap + breakout distance
Live risk	Enters late in extended moves, chop around VWAP	Roll behaviour	Works well with roll trigger — follows the move

> Avoid on days when NIFTY is oscillating within 50pts of VWAP — all three conditions rarely align and you get a late entry when the move is spent.

ATM_TRAP_REVERSAL

False-break specialist **Rare signal**

6/10
live suitability

Detects failed support breaks (seller trap) and failed resistance breaks (buyer trap). Requires a strong reversal candle body vs rolling average — 1.5x the 10-candle average body. Very precise when it fires, but needs 24 session candles to even activate.

Candles needed	24 session candles	Trap confirmation	3 candles to confirm fail, then body >= 1.5x avg
Live risk	Low frequency, misses entire sessions	False positive risk	Low — body multiplier filter is strict

> Only run on choppy, stop-hunt mornings. Not useful on clean trend days — it simply will not fire.

ATM_BREAKOUT_EXPANSION

Needs 45 candles **Afternoon only**

5/10
live suitability

Requires compression range <= 0.45% over 45 candles, a volume spike >= 1.8x average, ATR expansion >= 1.1x recent ATR, AND a close outside the breakout window high/low. All four must pass simultaneously.

Candles needed	45 — earliest fire ~10:15am	Conditions required	Compression + breakout + vol spike + ATR expansion

Live risk	Rarely fires — 4 conditions in 75 min is uncommon	When it fires	High conviction — each condition filters noise independently

> Not practical as a primary strategy. Use as a secondary confirmation layer or run alongside ATM_MULTI.

ATM_VWAP_REVERSION

Mean-reversion only **Risky on trend days**

5/10
live suitability

Fires on re-entry through VWAP after a deviation of 0.35%. Checks prior max/min deviation over 6 candles, then confirms previous close was on one side and current close crosses to the other. Correct logic — wrong context if the market is trending.

Candles needed	20 session candles	Deviation threshold	0.35% from VWAP over 6-candle lookback
Live risk	Full trend-day losses when market walks from VWAP	In ATM_MULTI	Already runs internally when ATR confirms sideways

> Do not run standalone on live. ATM_MULTI already uses this internally with ATR confirmation. Running it alone removes that protection.

ATM_IV_EXPANSION

Approximate IV only **Known code gap**

4/10
live suitability

Signal logic uses candle body expansion vs average body (1.8x multiplier) and RSI >= 55 near a recent key level. Does NOT read actual option chain IV — IV percentile is approximated from recent premium history. The IV gate in the entry filter is real, but the strategy signal itself is purely price-based.

Candles needed	30 session candles	Signal basis	Body size + RSI + key level — NOT real IV chain data
IV gate	Applied at engine filter, not inside this signal	Known gap	OI/option-chain ingestion missing from codebase

> The strategy name implies IV awareness but strategy.py uses body/RSI/price only. Avoid for live until option-chain data is added.

INTRADAY EQUITY — RANKED FOR LIVE USE

VWAP (single) or ADAPTIVE with VWAP + RSI

Recommended #1 **Fastest signal** **No warmup required**

9/10
live suitability

VWAP fires the moment close crosses VWAP — no rolling window needed. Score is abs(close - vwap) / close, so high scores only appear when price is meaningfully away from fair value. confirm_signal() adds a 3-candle window agreement check before any entry reaches the ranker.

Score formula	abs(close - vwap) / close	Confirmation	confirm_signal() requires 2 consecutive window agreements
Live risk	Choppy VWAP crossings mid-session	Config to tighten	MIN_RANKED_CANDIDATE_SCORE=0.012

> Best pairing: VWAP as primary signal, RSI as confirmation in ADAPTIVE mode with MIN_CONFIRMATIONS=2. This matches the code's own designed safety default.

ADAPTIVE (MA + RSI, min 2 confirmations)

Recommended #2 **Code default** **Overtrading protection**

8/10
live suitability

The README explicitly states that auto-adaptive normal-session intraday equity now requires both MA and RSI to agree. multi_strategy_signal() with min_confirmations=2 means at least 2 strategies must agree before an entry is ranked.

Agreement required	2 of selected strategies same direction	Score aggregation	Sum of all agreeing strategy scores
Ranking	agreement_count first, then score, then ATR	Best strategy set	MA + RSI, or VWAP + RSI, or MA + VWAP

> Use TOP 1 selection mode with this. Taking only the highest-ranked confirmed signal each scan is the safest live config the code supports.

ORB (equity)

Morning-only edge **No session filter**

7/10
live suitability

orb_strategy() checks the first 15 candles of the dataframe then fires on a close above/below that range. Score is price distance from the ORB boundary. Clean, objective signal with no ambiguity.

Candles needed	20 minimum (code check)	Range window	First 15 candles of loaded data slice

Score formula	(close - ORB high) / close for BUY	Live risk	Data slice must cover only today's candles

> Code gap: orb_strategy() uses df.iloc[:15] — not session-filtered. Verify your live data window covers only today before using standalone.

RSI (standalone)

High chop rate **Not recommended alone**

5/10
live suitability

rsi_strategy() fires BUY at RSI < 30, SELL at RSI > 70. Clean logic. Extreme RSI readings on 1m candles in liquid stocks are rare and can persist during strong trends — leading to premature counter-trend entries.

Buy threshold	RSI < 30	Sell threshold	RSI > 70
Score formula	(30 - rsi)/100 for BUY; (rsi - 70)/100 for SELL	Live risk	Counter-trend entries during persistent momentum runs

> Only use as a confirmation strategy inside ADAPTIVE mode — never as a standalone live strategy for intraday equity.

BREAKOUT (standalone)

Lagging score **Not recommended alone**

4/10
live suitability

breakout_strategy() checks if close > rolling 20-period high. The score formula uses prev_high = df["High"].rolling(20).max().iloc[-2] — that [-2] means the reference is one candle stale. Every signal fires one candle after the actual breakout.

Breakout ref	Rolling 20-bar high at iloc[-2] — 1 candle stale	Score formula	(close - prev_high) / close
Lag impact	Entry is always after breakout has occurred	Live risk	Slippage eats into every entry due to structural lag

> The [-2] index in the score formula is a structural code issue. Every BREAKOUT signal enters one candle late. Use only as a secondary confirmation filter.

MA (standalone)

Very slow **Needs 50 candles**

4/10
live suitability

ma_strategy() uses MA20 vs MA50. Needs 50 candles to warm up — nearly 1 hour of 1m data. The crossover almost never flips intraday. It reflects the day's trend direction, not a precise entry point.

Candles needed	50 (nearly 1 full trading hour)	Signal	MA20 crosses above/below MA50
Score formula	abs(MA20 - MA50) / close	Use case	Trend direction / regime filter only

> MA standalone for intraday is a trend-direction filter, not an entry signal. Run inside ADAPTIVE mode alongside VWAP or RSI, never alone.

PRACTICAL LIVE CONFIGURATION

Intraday options — recommended .env settings

Strategy	ATM_MULTI
Strike mode	ATM
Risk style	BALANCED
INTRADAY_OPTIONS_MAX_TRADES_PER_UNDERLYING	2
INTRADAY_OPTIONS_MAX_HOLD_MINUTES	60
INTRADAY_OPTIONS_ROLL_TRIGGER_PCT	1.5
INTRADAY_OPTIONS_THETA_EXIT_RATIO	0.4
INTRADAY_OPTIONS_TIME_EXIT_CUTOFF	14:30
INTRADAY_OPTIONS_MIN_RANGE_PCT	0.3
INTRADAY_OPTIONS_SIDEWAYS_LOOKBACK_CANDLES	8

Intraday equity — recommended .env settings

Mode	ADAPTIVE
Strategies	VWAP + RSI
Min confirmations	2
Entry selection	TOP 1
Risk style	BALANCED
One trade per symbol per day	YES
MIN_RANKED_CANDIDATE_SCORE	0.012
MIN_EDGE_TO_COST_RATIO	1.2
REVERSAL_EXIT_CONFIRMATION_CANDLES	2

`TRANSACTION_COST_MODEL_ENABLED`	1

All scores are derived from reading strategy.py, signal_scoring.py, and indicators.py directly. Recommendations reflect structural code properties — candle requirements, scoring formulas, confirmation gates, and known gaps — not backtested P&L.
